### Operating System Lab Week 3

**Question 1.** Keep in mind the utility of `fork()` and `exec()` system calls in process creation. Exec is

used to load a process and `fork()` creates a child process.

- In the xv6 directory, type “make qemu-gdb”, to start qemu along with GNU Debugger.
- Open another terminal window, type “gdb” while in the same xv6 directory. Enter “source .gdbinit”. Now gdb is connected to the xv6 operating system.
- In the same terminal (gdb), add a breakpoint for `exec` system call by typing “break exec”. Then type “continue” to reach the first instance where `exec()` is called. Typing continue again takes us to the next point where the `exec()` is invoked. Type continue the third time, and in the xv6 OS window run any shell command (`ls`, `cat` etc.)

#### Explanation of whole process:

First I executed command `make qemu-gdb` and after that open another terminal and types `gdb`

there. In next step, I wrote `source .gdbinit`, this connected my gdb to xv6 operating system.

```
(gdb) source .gdbinit
+ target remote localhost:26000
warning: No executable has been specified and target does
not support
determining executable automatically. Try using the "file
" command.
The target architecture is assumed to be i8086
[f000:fff0] 0xffff0: ljmp $0x3630,$0xf000e05b
0x0000fff0 in ?? ()
+ symbol-file kernel
warning: A handler for the OS ABI "GNU/Linux" is not built
into this configuration
of GDB. Attempting to continue with the default i8086 set
tings.
(gdb)
```

Now, I added breakpoint by typing `break exec` and then `continue`. It initiates our operating system and started first process `/init` as thread 2.

```
(gdb) break exec
Breakpoint 1 at 0x80100a80: file exec.c, line 12.
(gdb) continue
Continuing.
The target architecture is assumed to be i386
=> 0x80100a80 <exec>: endbr32

Thread 1 hit Breakpoint 1, exec (path=0x1c "/init",
    argv=0x8dffff0) at exec.c:12
12      {
(gdb) █
```

Again after `continue`, `init` started a shell process which is the `xv6` shell we get when the OS boots.

```
(gdb) continue
Continuing.
=> 0x80100a80 <exec>: endbr32

Thread 1 hit Breakpoint 1, exec (path=0x846 "sh",
    argv=0x8dffff0) at exec.c:12
12      {
(gdb) █
```

If you `continue` again, `gdb` will not return since it is waiting for a command to be started in the shell. Switch to the other window and try typing a command (for example, `ls`, `cat`) at which time you will get another break as the shell forks then execs the `ls` program.

```
Thread 1 hit Breakpoint 1, exec (path=0x846 "sh",
    argv=0x8dffff0) at exec.c:12
12      {
(gdb) continue
Continuing.
█
```

**screenshot of other terminal where I executed `ls` command**

exec dls failed

$ $ _
```

**Question 2.** On xv6 shell, type “ls” command. Your task is to make this command more user

friendly, by finding out what the numbers in the second column of the result represent.

The xv6 source code files are well documented using comments.

Edit the C file for this command, find out what the numbers in the second column represent (hint :

you might want to inspect the #included files) and modify the code appropriately so that it prints a

descriptive string in the second column instead of a number, when "ls" is called.

Note: every time you modify xv6, make has to be called again to implement those changes.

Write a document file whatever changes you have made along with the output screenshot

#### Explanation:

To make second column of ls command more use friendly. I did few changes in ls.c file from line 67 to line 73. Basically, First I find the meaning of status value(1, 2, 3) from stat.h header file. Then I use if-else in ls.c file as you can see in below screenshot from line 67. I changed second format specifier of line 69, 71, 73 with appropriate meaning as I found in stat.h header file.

```
42 }
43
44 switch(st.type){
45 case T_FILE:
46     printf(1, "%s %s %d %d\n", fmtname(path), st.type, st.ino, st.size);
47     break;
48
49 case T_DIR:
50     if(strlen(path) + 1 + DIRSIZ + 1 > sizeof buf){
51         printf(1, "ls: path too long\n");
52         break;
53     }
54     strcpy(buf, path);
55     p = buf+strlen(buf);
56     *p++ = '/';
57     while(read(fd, &de, sizeof(de)) == sizeof(de)){
58         if(de.inum == 0)
59             continue;
60         memmove(p, de.name, DIRSIZ);
61         p[DIRSIZ] = 0;
62         if(stat(buf, &st) < 0){
63             printf(1, "ls: cannot stat %s\n", buf);
64             continue;
65         }
66         //Changes done here (Assignment 3)
67         if(st.type == 2)
68             printf(1, "%s %s %d %d\n", fmtname(buf), "File", st.ino, st.size);
69         else if(st.type == 1)
70             printf(1, "%s %s %d %d\n", fmtname(buf), "Directory", st.ino, st.size);
71         else
72             printf(1, "%s %s %d %d\n", fmtname(buf), "Device", st.ino, st.size);
73         //end
74     }
75 }
76 break;
```

Then after saving ls.c file. I started qemu by make qemu command, and run ls command there.

#### Before Changes in ls.c:

```
sb: size 1000 nblocks 941 ninodes 200 nlog 30 logstart 2 inodestart 32 bmap star
